

One live call. Four technology boundaries. One source of truth.

Blue carries audio. Purple runs the agent. Green preserves the operation. Orange is the human control point.

No model response talks directly to Postgres: every write crosses the server-side domain boundary first.

A human mandate becomes a selected booking — without exposing the price cap.

The comparison happens server-side after two parallel carrier conversations.

WHAT REMAINS AUDITABLE

Call IDs · mandate version · each quote · selection rule · booking · notification outbox

If no valid offer arrives, the request remains recoverable; Tango does not manufacture a quote or a booking.

A pickup change is a guarded fork — not a freeform update.

The same registered carrier can reschedule only a window that remains inside the active mandate.

A new mandate reopens sourcing only when it invalidates the current booking.

The old booking stays visible until a valid replacement exists.

If no replacement quote is valid, the existing booking remains and the exception is escalated with the mandate and context.

Cancellation preserves history and stops future work; it never fabricates an external notification.

Client and carrier cancellation are distinct state transitions, shown as separate lanes.

CLIENT CANCELS

CARRIER CANCELS

CURRENT DEMO LIMIT

No email is implied by these cancellation paths.

The system records the cancellation and prevents future queued work. It does not claim the other party was notified or agreed.

Tango persists the context before it transfers the call to a human.

The handoff is a safe stop: the agent cannot silently turn an exception into approval.

FAIL-SAFE BEHAVIOUR

If transfer fails, the escalation is still durable and open for manual review. It is never interpreted as approval.

The recipient is data managed from Directory—not a phone number hardcoded in the runtime or a supervisor environment variable.
